

# NS-3 Simulation: Building Custom Topology Network Performance Evaluation

Ritika Thakur (2022408) — Swarnima Prasad (2022525)

## 1 Objective

To simulate a computer network using the NS-3 simulator and evaluate its performance. The network consists of multiple nodes, which include workstations, servers, and intermediate routers. Data packets are routed through the network, and links may have different capacities, delays, and noise levels.

## 2 Topology

The network consists of:

- 5 Workstations/Servers (N1, N2, N3, N4, N5)
- 4 Routers (R1, R2, R3, R4)
- Point-to-point links with varying capacities

The chosen topology for the simulation is shown below:

### 2.1 Network Topology

The network consists of 5 nodes (N1, N2, N3, N4, N5) and 4 routers (R1, R2, R3, R4). The links between them have the following capacities:

Link	Capacity
N1 – R1	1 Mbps
N2 – R2	1 Mbps
N3 – R3	3 Mbps
N4 – R4	1 Mbps
N5 – R3	1 Mbps
R1 – R2	3 Mbps
R1 – R3	2.5 Mbps
R2 – R4	1 Mbps
R3 – R4	1.5 Mbps

Table 1: Network Topology with Link Capacities

## 2.2 Traffic Matrix

The traffic matrix below shows the traffic rates between each pair of nodes (in Mbps).

	<i>N1</i>	<i>N2</i>	<i>N3</i>	<i>N4</i>	<i>N5</i>
<i>N1</i>	0	120	132	144	160
<i>N2</i>	100	0	190	111	154
<i>N3</i>	101	100	0	199	108
<i>N4</i>	150	156	262	0	159
<i>N5</i>	140	188	285	171	0

## 2.3 Node Information

Node	Node Number	Type
N1	0	Client/Server
N2	1	Client/Server
N3	2	Client/Server
N4	3	Client/Server
N5	4	Client/Server
R1	5	Router
R2	6	Router
R3	7	Router
R4	8	Router

Table 2: Node Details and Classification

# 3 Explanation of Packet Transmission and Routing

## 3.1 Packet Transmission

Each workstation (N1, N2, N3, N4, N5) is connected to a router (R1, R2, R3, R4) via point-to-point links. The workstations generate or consume data packets, while the routers handle routing packets to the appropriate destination.

### Example of Packet Flow

- **From N1 to N3:**
  - Packets from workstation N1 (Node 0) are sent to router R1 (Node 5) via the point-to-point link `n1r1`.
  - Router R1 forwards the packets through one of its links (`r1r3`) to reach the destination router for N3 (Node 2), which is R3 (Node 7).

Figure 1: Example of packet flow towards N3 (node 2)

During the simulation, tracing was enabled for all network events, including packet transmission, reception, enqueueing, dequeueing, and drops. The trace data was logged in a `.tr` file for detailed analysis. The generated trace file was parsed to calculate various statistics including one-way end-to-end delay, queue length and packets dropped.

### 3.2 Routing Packets Between Routers

The routers (R1, R2, R3, R4) are connected by point-to-point links with varying capacities and delays. Routing decisions are made based on the global routing tables, which are populated using the function:

```
Ipv4GlobalRoutingHelper::PopulateRoutingTables();
```

Source	N1	N2	N3	N4	N5	R1	R2	R3	R4
N1	—	R1	R1	R1	R1	—	—	—	—
N2	R2	—	R2	R2	R2	—	—	—	—
N3	R3	R3	—	R3	R3	—	—	—	—
N4	R4	R4	R4	—	R4	—	—	—	—
N5	R3	R3	R3	R3	—	—	—	—	—
R1	N1	R2	R3	R2	R3	—	R2	R3	R2
R2	R1	N2	R4	N4	R4	R1	—	R1	R4
R3	R1	R4	N3	R4	N5	R1	R1	—	R4
R4	R2	R2	R3	N4	R5	R3	R2	R3	—

```

```

## Routing Steps

1. The source router forwards the packet to the next-hop router based on the routing table.
2. The intermediate router examines the destination IP address and forwards the packet to the appropriate link.
3. This process continues until the packet reaches the destination workstation.

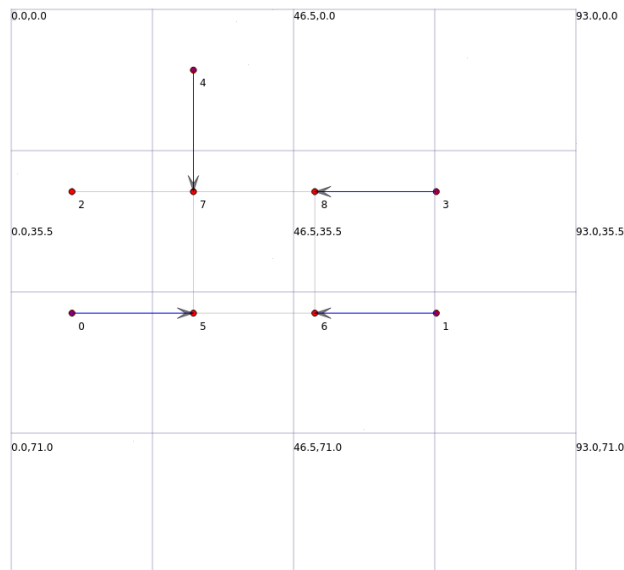

### 3.3 Queue Management

```

Figure 4: Average Delay and Variance of Delay

## 4 Simulation Parameters and Assumptions

### 4.1 Propagation Delay

In this simulation:

- A fixed propagation delay of **1 ms** is assumed for each point-to-point link.
- This delay is explicitly enforced in the code using the following configuration:

```
p2p.SetChannelAttribute("Delay", StringValue("1ms"));
```

- Every link in the topology is configured with this propagation delay, ensuring consistent timing behavior throughout the network.

### 4.2 Packet Generation Using Poisson Distribution

The arrival of packets in the simulation follows a **Poisson distribution**. Key characteristics of this distribution include:

- **Mean Interarrival Time ( $\lambda$ ):** The average time between the generation of two consecutive packets.
- The Poisson process is defined as:

$$P(k; \lambda) = \frac{\lambda^k e^{-\lambda}}{k!}$$

where  $P(k; \lambda)$  is the probability of  $k$  packet arrivals in a given interval, and  $\lambda$  is the rate of packet arrivals which is determined using the traffic matrix.

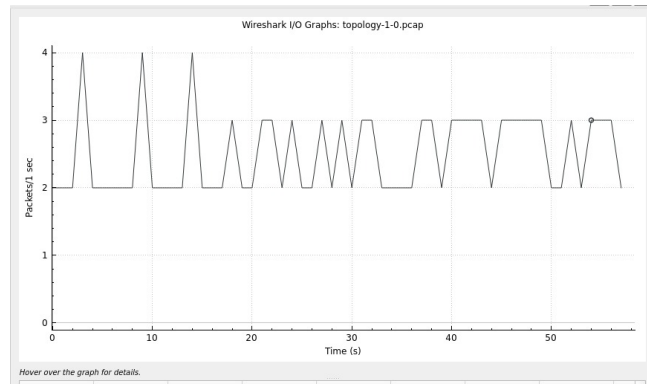

Figure 5: Poisson distribution for packet generation

- Packets are generated using an exponential inter-arrival time derived from the Poisson process:

```
ExponentialRandomVariable expRandomVariable;
double interArrivalTime = expRandomVariable.GetValue(meanArrivalRate);
```
